ALKYL HALIDE HYDROLYSIS IN AQUEOUS ALCOHOL-WATER MIXTURES--CORRELATION BETWEEN ACTIVATION PARAMETERS AND PARTIAL MOLAL QUANTITIES OF THE SOLVENT

1. INTRODUCTION

In the hydrolysis of alkyl halides in highly aqueous regions of alcohol-water mixtures, extrema in the observed enthalpy and entropy of activation with changes in solvent composition are often observed. $^{1-3}$ Numerous studies have tried to correlate solvent properties in the binary solvent system with these trends in enthalpies of activation. $^{4-7}$ The most general conclusions are as follows:

- a. In the highly aqueous region of alcohol-water mixtures, water structure has to break to form the transition state. This causes the energy of activation to increase, but the increase becomes less marked at higher temperatures. The enthalpies of activation generally decrease as the mole fraction of alcohol increases, and the enthalpies of activation reach minima at a specific solvent composition which corresponds to the maximum structure of water. As alcohol content increases further, parts of the tightly-bonded water structure start to break and the trend is reversed.
- b. Both ΔH_{S} (heat of solution of alkyl halides)⁵ and ΔH_{m} (heat of mixing of alcohol in water)⁴ are important factors affecting the observed extremum behavior of observed enthalpy of activation; and similarly, the corresponding quantities in entropies affect entropy of activation.
- c. When the substrate changes from ground to transition state, its solvation shell contributes to the observed changes in activation parameters; the effect is most marked in hydrolysis of the SNI nature. However, the specific structural changes involved in the reorganization step are difficult to determine.²

d. As the size of the alkyl group of the alcohol component increases, as in the case of t-butanol, unmixing of the two solvent components (microheterogeniety) is suspected to be present at a specific alcohol composition and temperature. This can explain the observed extrema in enthalpies and entropies of activation at that specific composition. 9,10

In this report we define the solvent structural changes which occur as one goes from the ground state to the transition state. We will show that the change in the enthalpy of activation as the alcohol content changes can be determined from the partial molal quantities of the solvent components. Published kinetic data on the hydrolysis of alkyl halides in alcohol-water mixtures are examined. We then define the solvent structural changes that occur in the transition state of these hydrolysis reactions in mixed solvents.

2. MODEL

STATISTICS STATES STATES SESSESS ASSESSED STATES

We first assume that the mechanism of the activation step is as follows:

R' X (solvated) + m
$$H_2O \longrightarrow [R'...X...(H_2O) m]^{\neq} + n ROH$$
 (1)

Since the solubilities of most alkyl halides increase as alcohol content increases, we assume that the alkyl halide substrate is solvated by alcoholic species (hydrogen bonded to water) in the solvent system. In the activation process, additional water molecules are expected to enter the solvation shell to assist the halide group leaving and to react with the substrate. Thus, some solvating alcohol molecules must leave the ground state solvation shell and give room to the entering water molecules. This unmixing and mixing of the solvent component contribute to the enthalpy changes in the activation step. The overall enthalpy change of this chemical process is the observed enthalpy of activation:

$$\Delta H_{\text{obs}}^{\neq} = \overline{H}_{R'X} \neq -\overline{H}_{R'X}^{g} + n\overline{H}_{ROH} - m\overline{H}_{H_{2}O}$$
 (2)

where $\overline{H}_{R'X} \neq$ and $\overline{H}_{R'X} g$ are the partial molal enthalpies of the solvated transition and ground states of the alkyl halide R'X, respectively.

By definition:

$$\overline{H}_{R'X}^{\neq} = \Delta H_{S}(\neq) + H^{O}_{R'X(\neq)}$$
(3)

$$\bar{H}_{R'X}^{g} = \Delta H_{s}(g) + H_{R'X(g)}$$
(4)

$$\overline{H}_{ROH} = \overline{L}_{ROH} + H^{O}_{ROH}$$
 (5)

$$\bar{H}_{H_2O} = \bar{L}_{H_2O} + H^O_{H_2O}$$
 (6)

where H^O is the molal enthalpy of the pure compound, and $\Delta H_{\rm S}(\neq)$ and $\Delta H_{\rm S}(g)$ are heats of solution of the transition and ground states of R'X, respectively. Substituting Equations (3) through (6) to Equation (2),

$$\Delta H_{\text{obs}}^{\neq} = \left[H_{\text{R'X}(\neq)}^{\circ} - H_{\text{R'X}(g)}^{\circ}\right] + n\overline{L}_{\text{ROH}} - m\overline{L}_{\text{H}_{2}O}$$

+
$$\left[\Delta H_{s}(\neq) - \Delta H_{s}(g)\right] + nH_{ROH}^{O} - mH_{H_{2}O}^{O}$$
 (7)

again, let

$$\Delta H^* = H^O_{R'X(\neq)} - H^O_{R'X(q)}$$

$$\Delta(\Delta H_s) = \Delta H_s(\neq) - \Delta H_s(g)$$

Equation (7) becomes

$$\Delta H_{\text{obs}}^{\neq} = \Delta H^{*} + n\bar{L}_{\text{ROH}} - m\bar{L}_{H_{2}O} + \Delta(\Delta H_{s}) + nH_{\text{ROH}}^{O} - mH_{2}^{O}$$
 (8)

As the composition of the bulk solvent changes from X_2 to X_2 + $^{\delta}X_2$ (a small change),

$$\delta\left(\Delta H^{\neq}_{\text{obs}}\right) = \delta(\Delta H^{*}) + \delta(n\bar{L}_{ROH}) - \delta\left(m\bar{L}_{H_{2}O}\right) + \delta\Delta(\Delta H_{S}) \tag{9}$$

where δ symbolizes the difference of a property between two solvent systems of different mole fractions.

Since the reaction mechanism remains the same when solvent composition changes, we can safely assume that the structure of the transition state remains the same. Therefore,

$$\delta(\Delta H^*) = 0$$

$$\delta(n) = 0$$

$$\delta(m) = 0$$

and

$$\delta\left(\Delta H^{\neq}_{ODS}\right) = n \delta\left(\overline{L}_{ROH}\right) - m \delta\left(\overline{L}_{H_2O}\right) + \delta\Delta(\Delta H_S)$$
 (10)

The last term in Equation (10), $\delta\Delta(\Delta H_S)$, is the change in the difference of heats of solution between the ground and the transition states of the pure substrate accompanying a change in solvent composition X_2 to X_2^* :

$$\delta(\Delta H_{S}) = \Delta H_{S}(\neq) - \Delta H_{S}(\varsigma) - [\Delta H_{S}'(\neq) - \Delta H_{S}'(\varsigma)]$$
 (11)

rearranging,

$$= \left[\Delta H_{S}(\neq) - \Delta H_{S}'(\neq)\right] - \left[\Delta H_{S}(g) - \Delta H_{S}'(g)\right]$$
 (12)

According to Arnett, 5 the ΔH_S for all solutes is endothermic in highly-aqueous alcohol-water mixtures relative to pure water. The value of ΔH_S increases as X_2 increases up to a specific value of X_2 , often denoted the "magic mole fraction". The value of ΔH_S becomes less endothermic as X_2 increases further. Since all solutes exhibit the same behavior, we conclude that the difference in heats of solution as X_2 changes is small and can be neglected. Thus, Equation (10) becomes

$$\delta \Delta H_{obs}^{\dagger} = n\delta \left(\bar{L}_{ROH} \right) - m\delta \left(\bar{L}_{H_2O} \right)$$
, and (13)

$$\Delta H^{\neq}_{obs} = C + n(\overline{L}_{ROH}) - m(\overline{L}_{H_2O})$$
 (14)

where

$$C = \Delta H^* + nH^O_{ROH} - mH^O_{H_2O}.$$

Equation (14) is consistent with the observation that the partial molal enthalpies of the solvent components are more indicative of the structure of the solvent mixture than the excess heat of mixing. 7

Ironically, Arnett measured the heats of solution of various solutes in alcohol-water mixtures in order to compute $\Delta H^{\not=}_{Obs}$. Arnett thought that the key parameters were ΔH_{S} of the ground state and the transition state. Arnett calculated $\Delta H_{S}(\not=)$ of t-butyl chloride in ethanol-water mixtures from $\Delta H^{\not=}_{Obs}$ - $\Delta H_{S}(g)$ for t-butyl chloride. The calculated values of $\Delta H_{S}(\not=)$ showed a complex variation with solvent composition which conflicts with Arnett's

measurements that ΔH_{S} of all solutes, ionic to hydrophobic, follow the same pattern as solvent components change. Thus, we contend that Arnett's view that

$$\Delta H_{\text{obs}}^{\neq} = \Delta H_{s}(\neq) - \Delta H_{s}(g)$$
 (15)

is incorrect because the contributions from the mixing and unmixing of the solvent components as one goes from ground state to transition state are ignored. We suggest that Equation (14) corrects this.

We now wish to introduce the quantity $\phi \textbf{L}_2$ defined as follows:

$$\phi L_2 = \bar{H}_2 - H_2^*$$
 (16)

which can be written as

$$\phi L_2 = \overline{L}_2 - \left(\overline{H}^* - \overline{H}^O_2\right) \tag{17}$$

where \overline{H}^* = the partial molal of enthalpy of component, Equation (2), in an infinitely dilute solution in water. Equation (14) can now be rewritten in terms of ϕL_2 as follows:

$$\Delta H_{obs}^{\neq} = C' + n \phi L_2 - m \overline{L}_{H_2O}$$
 (18)

where
$$C' = \Delta H^* + n\overline{H}_2^* - m\overline{H}_{2O}^O$$

Basically, the difference between Equations (14) and (18) is that the standard state for alcohol is an ideal solution of an infinitely dilute alcohol-water mixture as opposed to a pure alcohol solution. In pure solvent, alcohol forms polymeric hydrates $^{8-10}$

Al, A2, ... Ai, where the magnitude of i depends on the mole fraction and the specific alcohol. We assume that a small amount of pure substrate, RX, can be added without disturbing the equilibrium among the polymeric hydrates. The substrate, RX, is solvated by various polymeric hydrates so that RX is the substrate solvated by alcoholic hydrate, i. We further assume that only a specific RX can form the transition state so that alcohol has to be removed to form the appropriate solvated substrate, i.e.:

$$(RX)_{j} + mH_{2}O \xrightarrow{} (RX)^{\neq}$$

∴
$$(RX)_i + mH_2O \longrightarrow (RX)^{\neq} + nAi$$

 $(RX)^{\neq}$ rapidly forms products, and ΔH^{\neq} can be written as

$$\Delta H^{\neq} = \overline{H}(RX)^{\neq} - \overline{H}(RX)_{i} - m\overline{H}_{H_{2}O} + n\overline{H}_{Ai}$$
 (19)

Here $\bar{H}_{Ai} = \phi \cdot L_2$, since ϕL_2 arises from the heat of dilution of the solvent mixture at X_2 to an infinitely dilute solution in which only the monomonic specie is present; ϕL_2 was calculated to be the average heat of formation of the polymeric alcohol species hydrogen bonded to water (alcohol-hydrates). Therefore,

$$\Delta H^{\neq} = \overline{H}(RX)^{\neq} - \overline{H}(RX)_{i} - m\overline{H}_{H_{2}O} + n\phi L_{2}$$
 (20)

$$= \left[\bar{H}(RX)^{\neq} - \bar{H}(RX) \right]_{i} - m\bar{H}_{12}^{\circ} - m\bar{L}_{12}^{\circ} + n\phi L_{2}$$
 (21)

As X_2 changes, $\bar{H}(RX)^{\neq}$ and $\bar{H}(RX)_i$ remain the same since the reaction mechanism does not change. Thus,

$$\Delta H^{\neq} = constant \sim m\bar{L}_{H_2O} + n\phi L_2$$
 (22)

and the same relationship as Equation (18) is obtained.

We will try to demonstrate the relationship shown in Equation (18) for the following two groups of hydrolysis reactions:

- Group (A)--t-butyl chloride in methanol-water, ethanol-water, and t-butanol-water based on the data of Robertson and Sugamori 6 and of Moelwyn-Hughes. 13
- Group (B)--four types of alkyl halides in one solvent system, t-butanol-water, based on published kinetic data for t-butyl chloride, 6 l-adamantyl bromide, 14 cyclohexyl bromide, 15 benzylchloride.

In group (A), a tertiary carbon is present and the mechanism is SN1, while in group (B), various carbon centers from 1, 2, and 3 degrees to bridgehead carbon are compared in the same solvent system. The partial molal quantities of three alcohol-water systems are calculated from published data and listed in the Appendix.

3. RESULTS AND DISCUSSION

STATES ACCOUNT SERVICE STATES CONTROL SERVICE STATES STATES STATES

The calculations based on Equations (14) and (18) are listed in Tables 1-3 for group (A) and Tables 4-6 for group (B) (Table 3 is common to both groups). In all cases, Equation (18) was found to fit the data better than Equation (14), except in Table 1. We believe this is because methanol does not associate as strongly as the rest of the alcohols under examination. Since the methyl group is the least "hydrophobic" and methanol is the most polar among the alcohols, it may be that each single methanol molecule is hydrogen bonded to water molecules. This is shown in the smallest structure-promoting effect of methanol compared with larger alcohols.

3.1 Cases When m = 0.

When water molecules are not present in the activation step, m equals 0 and the mechanism is pure SN1. The hydrolyses of t-BuCl in both ${\rm EtOH-H_2O}$ (Table 2) and ${\rm tBuOH-H_2O}$ (Table 3) and of l-adamantyl bromide in ${\rm tBuOH-H_2O}$ (Table 4) fall into this mechanism, since both substrates contain a tertiary carbon. Thus, the model correctly predicts the pure SNl character.

The n Values.

To compare the n values among cases B-1 to B-4, it seems that n increases with the size of the alkyl groups in RX. This is consistent with our steric consideration that space for reaction with water is required and provided by the removal of solvated alcohol species from the substrate. The n value determined for each case remains constant over the X_2 range examined except at $X_2 = 0.02$ for case A-3. We will not speculate the reason for the change in n at $X_2 = 0.02$ in tBuOH-H₂O at the present time.

3.3 Activation Steps.

We can write the transition state for each case based on the values of m and n:

A-1 t-BuCl (solvated)
$$\longrightarrow$$
 $\left[\text{tBu}^{+\delta} \dots \text{Cl}^{-\delta} \dots \text{HOH(H}_2\text{O)}_5 \right]^{\neq} + \text{MeOH}$

A-2 t-BuCl (solvated)
$$\longrightarrow$$
 (tBu ... Cl) \neq + 2C₂H₅OH

A-3 t-BuCl (solvated)
$$\longrightarrow$$
 (tBu ... Cl) \neq + 2(t-BuOH)

B-2 Br (solvated)
$$\longrightarrow$$
 $\left(\bigcap ---- Br \right)^{\neq} + 4(t-BuOH)$

B-3 Br (solvated)
$$+\delta \stackrel{H}{\underset{\downarrow}{\stackrel{}{\downarrow}}} ---Br^{-\delta}$$
 + 2(t-BuOH)

Note that all of the transition state complexes are also solvated by the solvent system; presumably, the alkyl groups are surrounded by the alcoholic-water groups. We are concerned with the change in the solvation shell. The assumptions made in deriving Equations (14) and (18) should be reemphasized here. The relationships may not be applicable when

- a. The reaction mechanisms or products change as solvent composition changes.
- b. The difference in the heats of solution (which measure the extent of solvation) between the ground and the transition states of the alkyl halide substrate varies significantly with solvent composition.

For reactions of more compages mechanisms than the typical SN1 or SN2 model, additional patial molar enthalpy terms may be required in Equations (14) and (18) to account for variations in ΔH^{\neq} with solvent composition. Similar contributions of the quantities ΦS_2^e and \overline{S}_1 to the observed ΔS^{\neq} are expected.

The relationship

$$\Delta S_{obs}^{\neq} = constant - m\bar{S}_1 + n \phi S_2^e$$
 (23)

was found to be true among some of the above cases (e.g., for cases B-2 and B-3) 14 but was not as satisfactory as our results for ΔH^{\neq} , perhaps due to the greater uncertainties in obtaining the entropy data. However, since changes in enthalpy and entropy values are almost always compensatory, the same results should be expected for entropy of activation. We will not present our calculations for entropies in this report.

4. CONCLUSION

We have demonstrated a method to correlate the observed changes in ΔH^{\neq} for the hydrolysis of alkyl halides in aqueous alcohol-water mixtures with solvent composition to the structuralsensitive thermodynamic properties ϕL of alcohol and \overline{L} of water. The correlation can further reveal the specific changes involved in the structure of the solvation shells at the activation step. As direct, microscopic evidences of the structures of the solvated ground and transition states of the alkyl halides are hard to obtain, the thermodynamic treatment of the kinetic data employed by this method provides an alternative approach to the understanding of the solvent structural changes accompanying the reaction. A general phenomenum was observed in all of the reactions analyzed-that groups of the solvating alcohol species solvating the ground state have to leave to provide room for hydrolysis; the number of the leaving groups increases with the size of the alkyl group in the substrate. Water molecules participate in forming the transition states of substrates containing 1 or 2 degree carbon centers but are not present in the case of tertiary carbon.

APPENDIX

PARTIAL MOLAL QUANTITIES OF ALCOHOL (2)

AND WATER (1) COMPONENTS IN ALCOHOL-WATER BINARIES

Table A-1. MeOH - H_2O at 25 $^{\circ}C^1$

x ₂	ī. 2	Ī,
	cal/mole	cal/mole
0.226	-210	-152
0.307	-240	-200
0.400	~150	-243
0.585	- 85	-303
0.800	-30	-437

Table A-2. EtOH - ${\rm H_2O}$ at 10 ${\rm ^{\circ}C}^2$

<u>x</u> 2	$\frac{\phi L_2}{\text{cal/mole}}$
0.075	-2240
0.110	-1981
0.150	-1586
0.250	-844

Table A-3. tBuOH - H_2O at 26 °C, 38 °C, and 50 °C 3

x	cai/mole					
Temperature	26	38	50	26	38	50
0.02	-3885		-2495			
0.025	-3710		-2120	-22		-17
0.05	-2880	-2180	-1606	-98	-78.7	-60
0.08	-1875	-1405	-1029	-157	-120	-88.5
0.10	-1453	-1113	-810	-170	-126.3	-92.0
0.15	-873	-685	-502	-184	-150	-117.0
0.20	-564	-442	-320	-195		-121.0
